

MATH-243

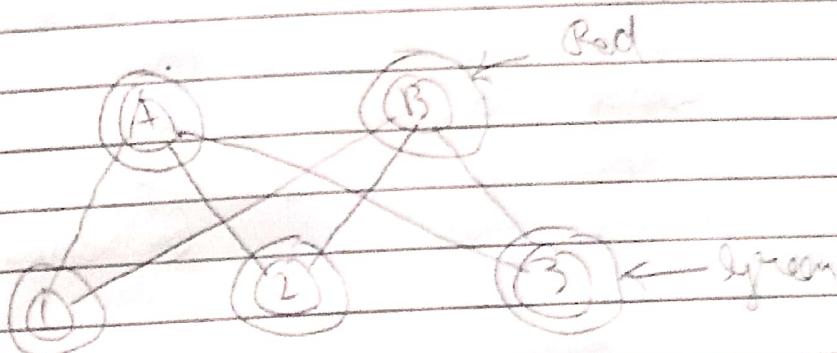

TEST #2

NAME: SRIYAS SRINIVASA

PALOMAR ID: 01295187

Ex. (a) $K_{2,3}$ GRAPH

Chromatic number

(a) 9 vertices, that have each of them nothing connected to other 9 in the graph.

9 vertices have degree 9, that have each of them nothing connected to other 9 in the graph.

Total number of edges of $K_{9,9}$ are 45, because there are 9 edges between 9 vertices to other set of 9 vertices, i.e. $9 \times 9 / 2 = 45$

2. Ans (a) Let $\frac{p}{q}$ be some irrational number. Then $\frac{p}{q} - 2$ is also irrational. Now $4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100$ are rational numbers.

$$\Rightarrow 27m^2 = 4(p+2)$$

$$\Rightarrow m^2 = 2(2p+1), \text{ which is not possible.}$$

Thus we have a contradiction.

i. Our assumption was, writing $2(m^2-2)$ is not divisible by 4 from any irrational number $\frac{p}{q}$.

(b) Let $(5+7\sqrt{2})$ is not irrational, let $(5+7\sqrt{2})$ be rational.

$$\Rightarrow (5+7\sqrt{2}) = \frac{p}{q}, \text{ for some coprime integers } p \text{ and } q.$$

$$\Rightarrow 7\sqrt{2} = \frac{p}{q} - 5 = \frac{p-5q}{q}$$

$$\Rightarrow \sqrt{2} = \frac{p-5q}{7q}$$

R.H.S is a rational number because the sum, product, quotient of two rational numbers is always rational;

but L.H.S is an irrational number.

(2)

P.T.O

It is a contradiction, as a rational and irrational number can never be equal.

Our assumption was wrong and $(\sqrt{17})/2$ is an irrational number.

3.4. (a) If the square of a number is an even integer, then the number is an even integer.

Proof :- Let the number a is not even.

Since a is not even $\Rightarrow a$ is odd.

$$\Rightarrow a = 2m+1; a \in \mathbb{Z}$$

$$\begin{aligned} \Rightarrow a^2 = (2m+1)^2 &= 4m^2 + 1 + 4m \\ &= 4m^2 + 4m + 1 \\ &= 2(2m^2 + 2m) + 1 \\ &\quad \underbrace{\quad}_{\in \mathbb{Z}} \end{aligned}$$

$$\text{Let } k = 2m^2 + 2m \in \mathbb{Z}$$

$$\Rightarrow 2k+1; k \in \mathbb{Z}$$

$$\Rightarrow a^2 \text{ is odd.}$$

Contradiction: a is even.

(a) If $x + y < 20$ then $x < 10$ and $y < 10$

Given $x = 3$ & $y = 10$ such that $x > y$

$$x + y > 10$$

$x > 10$ and $y < 10$

which will come back later. Let's try to think.

$$3. \text{ Given } a_m = 2^n - 1, n \geq 1$$

First five terms of the sequence is
for $n = 1, 2, 3, 4, 5$.

$$a_1 = 2^1 - 1 = 1$$

$$a_2 = 2^2 - 1 = 3$$

$$a_3 = 2^3 - 1 = 7$$

$$a_4 = 2^4 - 1 = 15$$

$$a_5 = 2^5 - 1 = 31$$

First five terms are: $1, 3, 7, 15, 31$

$$(ii) b_n = b_{n-1} + b_{n-2}, b_1 = 1, b_2 = 2, n \geq 3$$

$$b_3 = b_2 + b_1$$

$$= 3$$

$$b_4 = b_3 + b_2$$

$$= 3 + 2 = 5$$

$$b_5 = b_4 + b_3$$

$$= 8$$

$$b_6 = b_5 + b_4$$

$$= 13$$

$$b_7 = b_6 + b_5$$

$$= 21$$

Given terms are: 1, 2, 3, 5, 8, 13, 21, ...

$$\text{L.H.S. } q^3 + q^4 + \dots + q^m = \frac{q(q^m - 1)}{q - 1}, m \geq 3$$

$$\text{for } m=3$$

$$\begin{aligned} q^3 &= \frac{q(q^3 - 1)}{q - 1} \\ &= \frac{q \cdot (81 - 1)}{8} \end{aligned}$$

$$q^3 = 9 \cdot 81$$

Let it be true for $m=k$

$$q^3 + q^4 + \dots + q^k = \frac{q(q^k - 1)}{q - 1} \quad (1)$$

Now for $m=k+1$

$$q^3 + q^4 + \dots + q^{k+1} = q^3 + q^4 + \dots + q^k + q^{k+1}$$

From eqn (1) -

$$q^3 + q^4 + \dots + q^k = \frac{q(q^k - 1)}{q - 1}$$

(5)

$$q^3 + q^4 + \dots + q^{k+1} = \frac{q(q^k - 1)}{q-1} + q^{k+1}$$

$$= \frac{q \cdot q^k - q^3}{q-1} + q^{k+1}$$

$$= \frac{q^{k+1} - q^3 + 8 \cdot q^{k+1}}{8}$$

$$q^3 + q^4 + \dots + q^{k+1} = \frac{q(q^k - q^2 + 8 \cdot q^k)}{8}$$

$$q^3 + q^4 + \dots + q^m = \frac{q(q^k - q^2 + 8 \cdot q^k)}{8}$$

$$= \frac{q(9 \cdot q^k - q^2)}{8}$$

$$= \frac{q(9 \cdot q^k - q^2)}{8}$$

$$q^3 + q^4 + \dots + q^m = \frac{q(q^{k+1} - q^2)}{8}$$

Hence, it is also true for $n = k+1$

Hence, by induction :-

$$q^3 + q^4 + \dots + q^m = \frac{q(q^m - 1)}{8}$$

$$2A_m - a_m = 2A_{m-1} + 5 \Rightarrow A_0 = 1$$

$$\text{If } m=1, A_1 = 2A_0 + 5 = 7$$

$$\text{If } m=2, A_2 = 2A_1 + 5 = 19$$

⑥ All the factors P.T.O

$$\text{Given } a_n = 6(2^n) - 5$$

Prove by induction :-

$$\text{If } n=1, \text{ then L.H.S} = a_1 = 7$$

$$\text{R.H.S} = 6(2^1) - 5 = 7$$

$$\text{L.H.S} = \text{R.H.S} \text{ for } n=1.$$

∴ Result holds for case $n=1$.

By induction hypothesis, assume result is true.

$$\text{For } n=k, \text{ i.e. } a_k = 6(2^k) - 5 \quad (2)$$

Now, we prove result for $n=k+1$.

If we put $n=k+1$ in given data :-

We get :-

$$a_{k+1} = 2a_k + 5$$

Now, eqn. (2) (i.e. value of a_k)

$$\therefore a_{k+1} = 2(6(2^k) - 5) + 5$$

$$a_{k+1} = 6(2^{k+1}) - 10 + 5$$

$$a_{k+1} = 6(2^{k+1}) - 5$$

Which is the desired result.

Home, result is true for $n = k+1$

• By induction hypothesis:-

$$P_m = 6(2^m) - 5 \quad \forall m \geq 0$$

Let $P(m) = 2^m - 1$

To prove: $P(n)$ is divisible by 6.

$P(1) = 2^1 - 1 = 1$, which is divisible by 6.

As $P(1)$ is true.

Assumption:-

$P(m)$ is true, i.e.

$$P(m) = 2^m - 1 = 6k \quad (\text{where } k \text{ is some positive integer})$$

To prove $P(m+1)$ is also true for the next assumption,

$$P(m+1) = 2^{m+1} - 1 = 2^m \times 2 - 1$$

$$\Rightarrow (6k+1) \times 2 - 1, \text{ from } P(m) \text{ using } 2^m = 6k+1$$

$$\Rightarrow 6 \times 2k + 2 - 1 = 6 \times 2k + 1$$

$$\Rightarrow 6(2k+1) = 6k' \quad (\text{where } k' \text{ is some positive integer})$$

Since, we can show that $P(n+1)$ is also a multiple of 6 or divisible by 6.

∴ Our assumption is true.

This implies that $P(n) = 7^n - 1$ is always divisible by 6, for n belongs to natural numbers.

Q.E.D
The statement is true for $n=1$, because
 $1^2 = 1 = \frac{1(1+1)(2 \cdot 1 + 1)}{6}$

Let the statement be true for some natural number R .

$$\text{Then, } 1^2 + 2^2 + \dots + R^2 = \frac{R(R+1)(2R+1)}{6}$$

$$\text{Now, } 1^2 + 2^2 + \dots + R^2 + (R+1)^2$$

$$= \frac{R(R+1)(2R+1)}{6} + (R+1)^2$$

$$= \frac{R(R+1)(2R+1) + 6(R+1)^2}{6}$$

$$\Rightarrow \frac{(R+1)\{2R^2 + 7R + 6\}}{6}$$

$$\Rightarrow \frac{(R+1)(R+2)(2R+3)}{6}$$

$$\Rightarrow \frac{(R+1)\{(R+1) + 1\}\{2(R+1) + 1\}}{6}$$

This shows that the statement is true for the natural number ($n+1$) if it is true for n .

Also, the statement is true for $n=1$.

By the principle of mathematical induction, the statement is true for all $n \geq 1$.

T. Ans (a) This statement always holds true without \mathbb{Z} .

$$\begin{aligned} \text{If } P=2, \text{ then } P^2-1 &= 2^2-1 \\ &= 4-1 \\ &= 3 \text{ which is an odd number.} \end{aligned}$$

(b) If we choose two irrational numbers, say $\sqrt{8}$ & $\sqrt{2}$.

$$\text{Then, their quotient is } \frac{\sqrt{8}}{\sqrt{2}} = \sqrt{4} = 2$$

which is a rational number.

(c) If we choose any decimal number between 0 and 1, the answer will always come out to be greater than the number itself.

$$\frac{1}{25}$$

$$\Rightarrow \sqrt{\frac{1}{25}} = \frac{1}{5}$$

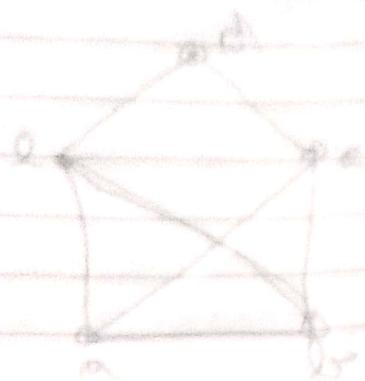

$$\therefore \frac{1}{5} > \frac{1}{25}$$

10

P.T.O

(10)

Überlappung von Knoten und Wegen

$$\deg(a) = \deg(b) = \deg(c) = \deg(d) = 3$$

$$\text{but } \deg(e) = 2 \neq 3$$

(11)
